Lung Ultrasound (LUS)

LUS is an ultrasound technique that is used to create an image of internal body structures LUNGS. Its aim is often to find a source of a disease or to exclude pathology. LUS signs, either alone or combined with other point-of-care ultrasound techniques, are helpful in the diagnostic approach to patients with acute respiratory failure, circulatory shock or cardiac arrest.

When LUS can be useful in ER
- Pleural pathology
- Pericardial pathology
- Shortness of breath
- Cyanosis
- Cough
- Shock

Objectives
1. To show the diagnostic capabilities of Lung Ultrasound in Critical Care.
2. To illustrate the diagnostic modalities needed.
3. To highlight the fields of application.
4. To encourage the use of standardized protocols and terminology.

LUS 10 signs

<table>

</tbody>
</table>

Two more signs, the lung pulse and dynamic air bronchogram, are used to distinguish atelectasis from pneumonia.

LUS monitoring can be performed at the bedside and used in mechanically ventilated patients to assess the efficacy of treatments, to monitor the evolution of the respiratory disorder, and to help the weaning process. LUS can be used for early detection and management of respiratory complications under mechanical ventilation, such as pneumothorax, ventilator-associated pneumonia, atelectasis and pleural effusions.
NORMAL Lung – A-line
The A-lines are horizontal artifactual repetitions of the pleural line displayed at regular intervals.

Lung CONSOLIDATION
Massive consolidation of the whole lower lobe without aerated lung tissue and no fractal sign.

PNEUMOTORAX
Abolished lung sliding “stratosphere sign”.

INTERSTITIAL Syndrome
Pulmonary interstitial edema is designed by diffuse lung rockets. Lung rockets are defined as at least 3 B-lines between two ribs.

Pleural EFFUSION
Quad sign (2D LUS)

Pleural EFFUSION
Sinusoid sign (M-mode)

LUNGs approach standardization

Examination technique
1. Patient in a semi-seated and sitting position for optimal access to posterior-basal lung segments.
2. Linear probe (7.5 -15 MHz) for study of pleural line and subpleural spaces.
3. Convex probe (3.5 -5 MHz) for B-line evaluation, consolidations and collapses.
5. Appropriate application (abdomen or vascular) with lung preset.
6. Correct general gain and TGC setting for better B-line representation.
7. Bilateral lung multiscansions at conventional thoracic lines and between them (parasteral, emiclave, LAA, LAM, LAP) plus posterior scans (scapula angular and paravertebral).

Lung point at the area at the junction between dead air (pneumothorax) and living air (inflating lung).

The longitudinal approach has the advantages of locating the pleural line in all circumstances.
CT vs LUS

<table>
<thead>
<tr>
<th>Lung CT</th>
<th>Lung ultrasound</th>
</tr>
</thead>
<tbody>
<tr>
<td>Thickened pleura</td>
<td>Thickened pleural line</td>
</tr>
<tr>
<td>Ground glass shadow and effusion</td>
<td>B-lines (multifocal, discrete, or confluent)</td>
</tr>
<tr>
<td>Pulmonary infiltrating shadow</td>
<td>Confluent B-lines</td>
</tr>
<tr>
<td>Subpleural consolidation</td>
<td>Small (centomeric) consolidations</td>
</tr>
<tr>
<td>Translobar consolidation</td>
<td>Both non-translobar and translobar consolidation</td>
</tr>
<tr>
<td>Pleural effusion is rare</td>
<td>Pleural effusion is rare</td>
</tr>
<tr>
<td>More than two lobes affected</td>
<td>Multilobar distribution of abnormalities</td>
</tr>
<tr>
<td>Negative or atypical in lung CT images in the super-early stage, then diffuse scattered or ground glass shadow with the progression of the disease, further lung consolidation</td>
<td>Focal B-lines are the main feature in the early stage and in mild infection; alveolar interstitial syndrome is the main feature in the progressive stage and in critical patients; A-lines can be found in the convalescence; pleural line thickening with uneven B-lines can be seen in patients with pulmonary fibrosis</td>
</tr>
</tbody>
</table>

The ultrasound bedside can read dynamically and constantly the air-fluid ratio which the CT scan cannot perform. Lung ultrasound is more sensitive than chest X-ray for the diagnosis of pneumothorax and shows similar high specificity.

LUS provide significant information to improve the management of the critical patient under mechanical ventilation, from the initial assessment, through the ventilation setting and its complication diagnosis, until the weaning process.

1. Diagnosis and stage of patient candidates for intubation (forced ventilation)
2. Patient follow up (no CT scan)
3. Monitoring and adapt fan therapy effectively by avoiding pneumothorax. Rf (Emergency Ultrasound Guidelines 2008) ACEP The medical use of US for diagnostic evaluation of emergency conditions and diagnoses, resuscitation of the acutely ill, critically ill or injured, guidance of high risk or difficult procedures, monitoring of certain pathologic states and as an adjunct to therapy.
Our best proposal for LUS

**MyLab™ OMEGA**

- Complete: High performance in all the applications
- Large probes portfolio, convex, linear and phased-array
- Advanced configurations, including TE probe or Strain package
- Fast: 2 probes connectors
- Compact: Up to 4 with multiconnector
- Connected: Touchscreen with intuitive menus
- Swivelling monitor
- Agile trolley easy with 4 swivelling wheels
- eTablet & MyLab™ Remote for remote storage and control
- Follow-up & Multi-modality options to retrieve other imaging modalities
- eStreaming for real-time imaging streaming

**MyLab™ SIGMA**

- High-frequency probe to scan lung parenchyma and commonly used in emergency for abdominal organs
- Low-frequency phased-array probe to scan lung and commonly used for heart functionality monitoring

**Systems/transducers cleaning & disinfection**

- Standard care involves handwashing or hand sanitization and use of sterile gloves.
- Droplet precautions include gown, gloves, headcover, facemask and eye shield.
- Airborne precautions add special masks (e.g. N-95 or N-99 respirator masks, or powered air purifying respirator - PAPR systems) and shoe covers.
- Equipment care is critical in the prevention of transmission. Cover probes and machine consoles with disposable plastic and forego the use of ECG stickers.

**Scientific references**

Pneumothorax can be a consequence of barotrauma, mainly when lung compliance is reduced. LUS is accurate in the diagnosis of pneumothorax (Lichtenstein et al. 2000) and is superior to supine anterior chest x-ray (Blaivas et al. 2005). The presence of real images (consolidation, effusion), of any pleural movement (sliding, lung pulse) or artefacts deriving from the visceral pleura (B-lines) rules out pneumothorax with 100% negative predictive value. If a static A pattern is visualized, a lung point must be searched moving the probe laterally and inferiorly: the lung point corresponds to the site where the collapsed lung goes back in touch with the parietal pleura and rules in pneumothorax with 100% positive predictive value. If no lung point is identified, the positive predictive value of a static A pattern alone ranges from 55 to 98%, depending on the clinical context; for example, if the lung is completely collapsed, no lung point can be visualised.
